

Ultra Beam

Dynamic Antenna Systems

- Electronically controlled HF antennas
- Top feature on all ham bands
- General coverage
- SWR 1:1 on all bands
- Interface to radio
- Updating the firmware

MOTOR-UNITS

New Motor Units use now a very exclusive and performing mechanics.

The Variable Reeling System (VRS) designed and produced by UltraBeam, now makes the Motor-Units unquestionably durable and highly reliable under any weather conditions and Through the years.

All antenna models (vertical,rigid dipole and yagi) are now equipped with the VRS system

All UltraBeam antenna-elements consist of a motor Units and two sections of hollow fiber Glass elements support tubes where the Copper-Beryllium strips are driven out to form the Desired lengths of each antenna element.

The decreasing thickness of each fiber glass tube has permitted to reduce the weight of Each half-element to 970 grams only and bestow extra flexibility and strength.

It is this weight/flexibility compromise that makes your UltraBeam very resistant to almost Any kind of wind. The total weight of each Motor Units is 4 kilos only.

About 100mm of each half of the fiber glass elements support tube Will be inserted in the fiber glass tube of the Motor Unit tube. As rubber boot blocks each half element in its position and seals the Junction point. Motor Units are so perfectly waterlight that no extra sealing is necessary.

Each half element is made of our conical fiber glass sections. When it is closed for shipping, the length Is 1,5 mt and about 5,3 – 5,4 mt when Fully extended.

THE BOOM

UltraBeam Yagis use square-section aluminium boom only.

Yagi antennas operating in the 6-20 mtr range use 60x60x3 mm booms.

3-element Yagis operating in the 6-30mtr and 6-40mtr ranges use 80x80x3 mm booms.

Extra reliable 80x80x4 mm booms are used for the 4-element Yagis operating in the 6-40 mtr range.

UltraBeam joint-system uses four 3mm steel plates and sixteen M8 bolts and is used on All booms.

The mechanical strength at each boom-joint point is even stronger than any other point across Each boom-section.

This unique joint system gives the boom the same mechanical stability as if were made of a Single length.

The 3 element 6-20mtrs antenna models do not need a truss and the remaining models are Provided with very effective trusses made of 6mm MastrAnt line.

3el 6-20mt Boom-to-Mast plate

4el 6-40mt Boom-to-Mast plate

Mast-to-Boom plates (except the one for the 2el 6-20 mtr) are made stainless steel and Dimensioned in accordance with the antenna model.

Stainless steel U-bolts have the following diameters:

2 elements 6-20mtr = N° 2 x 50mm

3 elements 6-40mtr = N° 4 x 50/60/65*mm

4 elements 6-40mtr = N° 4 x 65mm or more**

3 elements 6-20mtr = N° 4 x 50mm

4 elements 6-20mtr = N° 4 x 50/60/65*mm

* One of the diameters has to be specified in the order.

** To be specified in the order.

MOTOR UNITS ASSEMBLY

No HF antenna has ever been so easy and speedy to assemble as UltraBeam. You can install your UltraBeam very easily, quickly and, above all, without the need of reading useless pages and pages of installation instructions. The exact positions of each Motor Unit is indicated by coloured labels on the boom.

Each Motor Unit is fixed on the boom by 4mm aluminium plate. Motor Unit plates are fixed by four M6 bolts and two stainless plates (stirrups) on the bottom side of the boom. This effective method avoids to perforate the boom and, above all, it guarantees that the Boom-plate remains firmly fixed to the boom.

All Motor Units are fixed to its aluminium support plate by eight stainless M5 bolts. As all nuts are self-blocking, just tighten each bolt until a light pressure is noticed on the gasket. Do not over tight.

Unlike the Motor Units for the passive-elements, the Driven Element Unit is provided with is an efficient 2:1 Balun (25-50 Ohms). As the typical antenna impedance is 25 Ohms, a Balun is essential in order to have a perfect match (SWR 1:1) between the antenna and its the feed-line.

Motor Units used in each passive-element are indicated. Although they are distinguished by Coloured labels they are perfectly identical both eletronically and mechanically.

The presence of a multi-pin IP68 panel-socket on every Motor Unit makes its removal extremely speedy and comfortable in any moment.

All connectors are perfectly waterproof and do not need any extra sealing. UltraBeam does not recommend any extra sealing materials.

PLUG-IN ANTENNA CONTROL WIRING CABLE

IP68 connectors used in the Plug-in Antenna Control Wiring Cable permit a quick connection between the Antenna Controller and the antenna. You only need to insert each IP68 connector to its related Motor Unit, the DB25 Connector to the Antenna Controller and your antenna is ready to be used.

Each Plug-in Antenna Control Wiring Cable is made and tested by UltraBeam. For this reason the control cable is delivered with the DB25 connector soldered to its end. If removing the DB25 is necessary to get the cable to your radio-room, be careful when taking note of each coloured wire and its related pin-numbers. To avoid any mistake we suggest to cut the cable a few centimeters from the DB25 and re-solder the wires one by one. Unsolder one piece of wire from the DB25 connector and solder the wire with same colour to the same pin. Repeat this operation for each wire of the control cable.

The connection wiring between the antenna control cable and each four-conductor cable from each Motor Unit is made at the UltraBeam factory and sealed by a special "Y" thermo-shrinkable material.

This connection between Motor Units and control cable is perfectly watertight and no extra sealing is necessary. As each control cable has its own length, you only need to lay each cable along the boom and fix by tape or tie wraps.

Each connector is marked by a colour, therefore, the connections are both easy and unequivocal.

NOTE :

Connectors are the excellent IP68 made in USA by SwitchCraft. As these connectors are absolutely watertight at any temperature and weather condition, UltraBeam does not recommend to use any sealing material either on the connectors or on any part of the Motor Units.

Although each Motor Unit is accurately tested at the factory, we

highly recommend you to carry out an electrical check to verify that no damage has occurred during transportation.

NOTE :

Do not insert the rubber boots on the Motor Units until you run the test.

MOTOR UNIT ELECTRICAL TEST

Switch ON the Antenna Controller and wait until "ELEMENT RETRACTED" is displayed.

Press "MENU" and confirm by "YES" (30m button).

Press again "MENU" to retract.

IMPORTANT:

Before running the test and especially before you use the antenna, be sure to have the DB25 connector firmly screwed to the Antenna controller.

YAGI ELEMENTS OPERATING ON 6-40 MTRS

Elements used by Yagis antennas operating in the 7-50 MHz range are about 21,5 meters long. For these types of antennas UltraBeam has designed an adequate and very reliable element support mechanics. Elements are not supported by the Motor Units, but simply by a very strong aluminium structure fixed on the boom. Unlike the 6-20mtrs types, the only task of the Motor Units used for the 6-40mtr antennas is to drive the Copper-Beryllium strips along the fiber-glass tubes. As each element supporting structure is the only part in charge of holding up the whole weight and the mechanical stress of the related antenna-element (Motor Units are not involved with any mechanical stress), it makes the removal of the Motor Units extremely easy and speedy. The unique boom-to-element support system, designed and developed by UltraBeam, gives you the possibility to assemble each antenna-element on the ground and fix them very comfortably to the boom successively. This important possibility, at times, becomes particularly decisive when space is very limited.

Each half antenna-element (Left and right) consists of three pieces: a fiber-glass telescopic tube (1) (also used on the 6-20mtr yagis) and two 2,7 mt cylindrical fiber-glass tubes. The fiber-glass tubes are joint together by a short stainless-steel tube also used as an anchorage point for the vertical Trusses (furnished with the antenna) of the antenna elements.

Gli elementi 2-3 hanno un diametro di 48mm e uno spessore di 3 mm.

1) elemento telescopico 5,4 mt.
2-3) elemento cilindrico 2,7 mt.

6-20 MTR & 6-40 MTR VERTICAL ANTENNAS

UltraBeam vertical antennas use a single Motor Unit and a vertical telescopic fiber-glass tube. Both antenna types operate as full-size $1/4$ wave lambda on any frequency. Unlike rigid dipoles or Yagis, the impedance is determined by the ground (radials). Radials must be made of copper wires and have a length of $1/4$ lambda on each operating band. Remember: the more the radials, the higher the efficiency of the antenna. The Motor Unit will be fixed to a aluminium tube (delivered with the antenna) provided with a lathed bush. The aluminium tube is 1 meter long and can be installed anywhere. The 6-20mtr vertical antenna can be assembled and installed very quickly because it has a single 5,4 meter telescopic element and therefore no guys are needed.

The 6-40 mtr vertical antenna, instead, uses four further 1,3mt fiber-glass tube sections and its total length is slightly over 10 meters.

This antenna needs one set of 4 guys anchored to its middle.

The guys can be made of 3-4mm nylon strings or any other non-conductive material. The element is provided with a fifth wheel to anchor the set of guys.

Like all other UltraBeam antennas, the Motor Units for the vertical antennas are also equipped with the Variable Reeling System (VRS).

The Antenna Controller for the vertical antenna is identical to that used for Yagi antennas, but equipped with a single Drive-Board and a dedicated Software.

All default lengths are purely indicative and, depending on the location, they always need to be modified for best resonance.

Dynamic Antenna Systems

CONTROLLER

- 1) RS-232 : firmware up-grade and interface to RTX .
- 2) DB-25 : connection to Motor Units.
- 3) 24-35 DCV input.

Well aware that the most effective dynamic antenna system can only be possible primarily through the effectiveness of its dedicated antenna controller, major priority has been given to utmost performance and reliability of this very important device.

This is well evidenced by the discrete components used in lieu of common and, consequently, cheap integrated circuits.

Each Motor Unit, in fact, is driven by a very reliable driver-board equipped with eight transistors capable of handling 10 Amps in case of accidental short-circuit.

The RS-232 port permits to upgrade the firmware for free at any moment. You can download the latest upgrade from: <http://www.ultrabeam.it/download1.html> by simply connecting a pin-to-pin serial cable between the Antenna Controller and your computer.

Furthermore, you can use the RS-232 port to interface your RTX to the Antenna Controller.

By a dedicated cable (optional) your antenna can now track the frequency you tune on on your RTX. By entering the Menu, you can also select either the Band-Switching or the Band-&-Frequency function.

While an easy and very intuitive software interface permits anyone to use the Antenna Controller without the need of reading its Instruction Manual, its large LCD display shows each Menu-page and its related functions.

In accordance with the antenna-type (vertical, rigid-dipole or yagi), an appropriate software will be installed in the Antenna Controller. This will permit the antenna element (in the case of a vertical or a rigid-dipole) or elements (in the case of a yagi) to reach the default lengths for perfect resonance on the operating frequency.

In most cases, however, the awesome 50 Ohms impedance necessary to obtain an SWR of 1:1 can only be obtained by slightly modifying the default lengths (normally by very few centimetres) of the driven element. You can perform this operation within a couple of seconds only and while sitting comfortably in front of your radio equipment. Once the operation has been completed, the CPU can now store the optimized length for ideal antenna-resonance on the whole antenna operating range.

The time necessary to band-changes is very short. When starting from its fully-retracted condition, the antenna only needs 18 seconds to reach the due length on the 20 metre-band.

Apart the shorter time needed to switch from an operating band to another, the movement of the antenna is signalled by a bar-graph, a flashing band-led and an acoustic signal (bip) you can either switch-off or adjust through the Menu
